## Abstract

22        *Tegillarca granosa* (Linnaeus, 1758), commonly known as blood cockles, is one  
23 of the most well-known marine bivalve for its nutritional benefits and economic  
24 significance. Determining their sex is essential for maintaining a balanced male-  
25 to-female ratio, which is crucial for preventing overexploitation of this shellfish  
26 resource. The sex-determining mechanism in the shell morphology of bivalves is  
27 challenging macroscopically due to the limited literature regarding this expertise.  
28 In addition, no current technologies are employed to classify the sex based on shell  
29 morphology. This study proposes a machine learning approach for classifying the  
30 sex of blood cockles using various linear measurements (length, width, height,  
31 distance between the hinge line, distance between umbos, and rib count) and  
32 angles (dorsal, ventral, anterior, posterior, left lateral, and right lateral) collected  
33 from male and female specimens. Available machine learning models in MATLAB  
34 were trained to discern sexual dimorphism. Among the models, Linear SVM  
35 performed best, achieving an accuracy of 69.80%, precision of 69.82%, recall of  
36 69.80%, and an F1-score of 69.73%. Feature importance analysis indicated that  
37 the distance between the umbos and height were the most significant features.

<sup>109</sup> **Chapter 1**

<sup>110</sup> **Introduction**

<sup>111</sup> **1.1 Overview**

<sup>112</sup> The Philippines is a global center of marine biodiversity and has established aqua-  
<sup>113</sup> culture as a significant contributor to total fishery production (Aypa & Baconguis,  
<sup>114</sup> 2000; BFAR, 2019). The country produces over 4 million tonnes of seafood annu-  
<sup>115</sup> ally and is the 11th largest seafood producer in the world. Aquaculture is deeply  
<sup>116</sup> integrated into Filipinos' livelihoods, encompassing fish cultivation and the pro-  
<sup>117</sup> duction of various aquatic species, including bivalves. Among these, blood cockles  
<sup>118</sup> (*Tegillarca granosa*) hold considerable economic and environmental significance,  
<sup>119</sup> making it essential to ensure sustainable production and population balance.

<sup>120</sup> Maintaining a balanced male-to-female ratio of blood cockles is crucial to pre-  
<sup>121</sup> vent overharvesting and ensure sustainability. An imbalanced ratio can lead to  
<sup>122</sup> overexploitation and negatively impact the population's viability. However, there  
<sup>123</sup> is limited literature on *T. granosa* that provides a thorough understanding of its  
<sup>124</sup> sex-determining mechanisms, particularly regarding sexual dimorphism based on  
<sup>125</sup> morphological and morphometric characteristics (Breton, Capt, Guerra, & Stew-  
<sup>126</sup> art, 2017).

<sup>127</sup> Currently, sex determination methods for blood cockles are invasive, including  
<sup>128</sup> dissection and histological examinations, which often result in the death of the  
<sup>129</sup> species. While there is growing literature on sex identification in aquaculture  
<sup>130</sup> commodities using machine learning and deep learning, there is a notable scarcity  
<sup>131</sup> of research specifically addressing *T. granosa* (Miranda & Ferriols, 2023).

<sup>132</sup> This study, titled "Morphometric-Based Non-Invasive Sex Identification of

<sup>133</sup> Blood Cockles *Tegillarca granosa* (Linnaeus, 1758)," aims to provide a detailed  
<sup>134</sup> baseline analysis of blood cockles by leveraging their morphological and morpho-  
<sup>135</sup> metric characteristics. Sexual dimorphism in bivalves is often subtle and chal-  
<sup>136</sup> lenging to establish mascropically (Karapunar, Werner, Fürsich, & Nützel, 2021).  
<sup>137</sup> However, by integrating machine learning and deep learning, the study seeks to  
<sup>138</sup> identify distinct features that may indicate sexual dimorphism between male and  
<sup>139</sup> female blood cockles.

## <sup>140</sup> 1.2 Problem Statement

<sup>141</sup> Identifying the sex of *T. granosa* is important for promoting sustainable aquacul-  
<sup>142</sup> ture and biodiversity by maintaining a balanced male-to-female ratio. A balanced  
<sup>143</sup> ratio helps prevent overharvesting. Although sex identification is crucial for blood  
<sup>144</sup> cockle population management and sustainable aquaculture, there is a notable  
<sup>145</sup> lack of research on creating non-invasive methods for determining the sex of *T.*  
<sup>146</sup> *granosa*. Many recent studies and approaches rely on invasive methods like dis-  
<sup>147</sup> section or histological analysis, which are impractical for large-scale aquaculture  
<sup>148</sup> operations focused on conservation.

<sup>149</sup> Current methods for determining the sex of *T. granosa* are invasive and in-  
<sup>150</sup> volve dissection, which requires cutting open the shell to visually inspect the  
<sup>151</sup> gonads (Erica, 2018). This procedure can cause harm to the specimens and fre-  
<sup>152</sup> quently leads to their death. Another method is histological examination, where  
<sup>153</sup> tissue samples are analyzed under a microscope (May, Maung, Phy, & Tun,  
<sup>154</sup> 2021). Both approaches are labor-intensive and time-consuming, and can pose  
<sup>155</sup> risks to population management, particularly when maintaining a balanced sex  
<sup>156</sup> ratio for breeding programs is essential. Moreover, these invasive methods require  
<sup>157</sup> specialized technical skills for accurate execution. Resource-limited aquaculture  
<sup>158</sup> operations face significant challenges in accessing the necessary laboratory equip-  
<sup>159</sup> ment, such as microscopes and staining tools, complicating the process.

<sup>160</sup> A less invasive approach employed by aquaculturists involves monitor spawning  
<sup>161</sup> behavior, where individuals are separated and stimulated to reproduce in order  
<sup>162</sup> to determine their sex through the release of gametes (Miranda & Ferriols, 2023).  
<sup>163</sup> Although this method is indeed less invasive than dissection, it still induces stress  
<sup>164</sup> in blood cockles and may not be completely effective for fast identification in large  
<sup>165</sup> populations.

<sup>166</sup> Given the limitations of both invasive and less invasive methods, there is a  
<sup>167</sup> clear need for a more advanced approach. An alternative, non-invasive method

<sub>168</sub> involving machine and deep learning technologies could address these issues by  
<sub>169</sub> providing a fast, accurate, and effective solution without harming or stressing the  
<sub>170</sub> blood cockles.

## <sub>171</sub> 1.3 Research Objectives

### <sub>172</sub> 1.3.1 General Objective

<sub>173</sub> The general objective of this study is to develop a non-invasive method for iden-  
<sub>174</sub> tifying the sex of *Tegillarca granosa* using machine and deep learning integrated  
<sub>175</sub> with computer vision technologies. This method aims to provide accurate and  
<sub>176</sub> streamlined sex identification without causing harm to the specimens, thus sup-  
<sub>177</sub> porting sustainable aquaculture practices.

### <sub>178</sub> 1.3.2 Specific Objectives

<sub>179</sub> To achieve the overall general objective of developing a non-invasive sex identifi-  
<sub>180</sub> cation of *T. granosa* using machine learning, deep learning, and computer vision  
<sub>181</sub> technologies, the following specific objectives have been established:

- <sub>182</sub> 1. To collect and organize a comprehensive dataset of *T. granosa* which will  
<sub>183</sub> include high-quality images and relevant morphological measurements that  
<sub>184</sub> will serve as the basis for the machine-learning model.
- <sub>185</sub> 2. To develop and implement machine learning models that can classify the  
<sub>186</sub> sex of *T. granosa* based on the collected linear measurements and images of  
<sub>187</sub> different angles of the sample.
- <sub>188</sub> 3. To evaluate the performance of the models used using performance metrics  
<sub>189</sub> such as accuracy, precision, recall, and F1-score.
- <sub>190</sub> 4. To develop a system that can identify the sex of *T. granosa* based on its  
<sub>191</sub> morphological characteristics.

## **192 1.4 Scope and Limitations of the Research**

193 This study is conducted alongside the ongoing research by the UPV DOST-  
194 PCAARRD, titled "Establishment of the Center for Mollusc Research and De-  
195 velopment: Development of Spawning and Hatchery Techniques for the Blood  
196 Cockle (*Anadara granosa*) for Sustainable Aquaculture." The ongoing research pri-  
197 marily involves the rearing of *T. granosa* from spat to larvae, as well as feeding  
198 experiments, stocking density evaluations, substrate selection, and settlement rate  
199 assessments.

200 In contrast, this study mainly focuses on developing a non-invasive method for  
201 identifying the sex of *Tegillarca granosa* using machine learning, deep learning,  
202 and computer vision technologies. The goal is to provide an accurate and efficient  
203 means of sex identification without causing harm to the samples, contributing to  
204 sustainable aquaculture practices.

205 The researchers work with 500 already sex-identified blood cockles taken from  
206 Panay Island, specifically from Zarraga Iloilo and Ivisan Capiz. These samples,  
207 equally divided between 250 males and 250 females, were obtained through in-  
208 duced spawning via temperature shock and dissection. Samples subjected to data  
209 collection of *T. granosa* are only limited to the spawned stage among the five go-  
210 nadal stages - immature, developing, mature, spawning, and spent stages. The  
211 other stages are not preferable due to indistinguishable gonads and their inabil-  
212 ity to perform induced spawning (May et al., 2021). Thus, the researchers only  
213 focused on the samples undergoing the spawned stage.

214 In collecting the data, the researchers will personally gather linear measure-  
215 ments, including length, width, height, rib count, length of the hinge line, and  
216 distance between the umbos through the vernier caliper. Images of the speci-  
217 mens, captured from various angles, will also be gathered under the supervision  
218 of University Research Associates from the Institute of Aquaculture, College of  
219 Fisheries and Ocean Sciences. Collection of the images of the sample is non-  
220 invasive due to the blood cockle-built ability to survive in low oxygen areas and  
221 having the intertidal mudflats as their natural habitat (Zhan & Bao, 2022).

222 The method developed in this study is specific to *Tegillarca granosa* and may  
223 not be applicable to other bivalve species. The model will be trained exclusively  
224 for *Tegillarca granosa* and morphological features including length, width, height,  
225 rib count, length of the hinge line, and distance between the umbos may not be  
226 consistent across other shellfish species.

## **227 1.5 Significance of the Research**

228 This study will give us a significant advancement in non-invasive sex identifica-  
229 tion methods in *T. granosa* providing innovative solutions that could solve the  
230 challenges in identifying sex and reshape sustainable approaches to aquaculture.  
231 The significance of this study extends to the following:

232       *Research Institution.* The result of this study focusing on the sex-identification  
233 mechanism of bivalves, specifically *Tegillarca granosa*, will provide valuable in-  
234 sights into universities and research centers that focus on fisheries and coastal  
235 management, such as the UPV Institute of Aquaculture, that aim to develop  
236 sustainable development and suitable culture techniques.

237       *Fishermen.* By developing a non-invasive method in sex identification, this  
238 study can help long-term harvest efficiency and maintain the ratio of the harvest  
239 which can help prevent overexploitation of the *T. granosa*.

240       *Coastal Communities.* The result of this study would be beneficial for the  
241 coastal communities that are reliant on their source of income with aquaculture  
242 commodities like blood cockles. Maintaining the diversity and aspect ratio of  
243 male and female may increase the market value of blood cockle production since  
244 cockle aquaculture faces significant obstacles worldwide due to the fluctuating  
245 seed supplies and scarcity of broodstock from the wild.

246       *Future Researchers.* The result of this study would serve as the basis for studies  
247 that involve sex identification in bivalves such as *T. granosa*. Some technologies  
248 are yet to be explored in machine learning, deep learning, and computer vision  
249 technologies that can lead to higher accuracy and distinguish the presence of  
250 sexual dimorphism in the *T. granosa*.

<sup>251</sup> **Chapter 2**

<sup>252</sup> **Review of Related Literature**

<sup>253</sup> Aquaculture is the fastest-growing industry in animal food production and has  
<sup>254</sup> great potential as a sustainable solution to global food security, nutrition, and  
<sup>255</sup> development (*FAO 2024 Report: Sustainable Aquatic Food Systems Important*  
<sup>256</sup> *for Global Food Security – European Fishmeal*, 2024). Aquaculture is deeply in-  
<sup>257</sup> tegrated into the livelihoods of Filipinos, not only through fish cultivation but  
<sup>258</sup> also through the production of other aquatic species, including mollusks, oysters,  
<sup>259</sup> clams, scallops, and mussels (Breton et al., 2017). Mollusks, particularly blood  
<sup>260</sup> clams *Tegillarca granosa*, have economic and environmental significance. It has  
<sup>261</sup> been a collective effort to maintain an ideal male-to-female ratio to avoid overhar-  
<sup>262</sup> vesting and maintain the optimal ratio to preserve the population and production  
<sup>263</sup> of the blood cockles.

<sup>264</sup> The members of the Arcidae Family, including *T. granosa* are important  
<sup>265</sup> sources of food and livelihood. Cockle aquaculture meets rising demands, however,  
<sup>266</sup> it faces significant challenges due to fluctuating seed supplies (Miranda & Ferriols,  
<sup>267</sup> 2023). To solve the problem, researchers exert a considerable amount of effort,  
<sup>268</sup> developing a broader understanding of bivalves, including their sex-determining  
<sup>269</sup> mechanism, due to their notable importance in terms of diversity, environmental  
<sup>270</sup> benefits, and economic and market importance (Breton et al., 2017). Despite the  
<sup>271</sup> promising idea of identifying sex, there is limited research reported in terms of  
<sup>272</sup> sexual dimorphism, making it harder to distinguish through its morphological and  
<sup>273</sup> morphometric characteristics.

<sup>274</sup> By addressing the challenges in the sex identification of *T. granosa*, it would be  
<sup>275</sup> able to address one problem at a time. Currently, there are no recent documented  
<sup>276</sup> publications that integrate machine learning and computer vision in characterizing  
<sup>277</sup> sexual dimorphism, reducing complexity, variability in sex determination, and

<sup>278</sup> differentiation mechanisms in bivalves, including *T. granosa* specifically.

## <sup>279</sup> 2.1 Background on *Tegillarca granosa* and Their <sup>280</sup> Importance

<sup>281</sup> *Tegillarca granosa* (Linnaeus, 1758) is also known as blood cockles or blood clam.  
<sup>282</sup> In the Philippines, it is commonly known as a Litob, a marine bivalve species from  
<sup>283</sup> the family Arcidae. Litob is widely distributed in the world including Southeast  
<sup>284</sup> Asia. They can be found in the intertidal mudflats adjacent to the mangrove forest  
<sup>285</sup> (Srisunont, Nobpakhun, Yamalee, & Srisunont, 2020). With the intertidal mudflat  
<sup>286</sup> as *T. granosa*'s habitat, they experience severe hypoxia or low oxygen levels in the  
<sup>287</sup> blood tissues during the tidal cycle. The blood clams exhibit a unique red-blood  
<sup>288</sup> phenotype where it serves two purposes the hemocyte carries oxygen around the  
<sup>289</sup> body and strengthens immune defenses. In addition, it possesses a unique ability  
<sup>290</sup> to absorb oxygen at similar rates in water and air (Zhan & Bao, 2022).

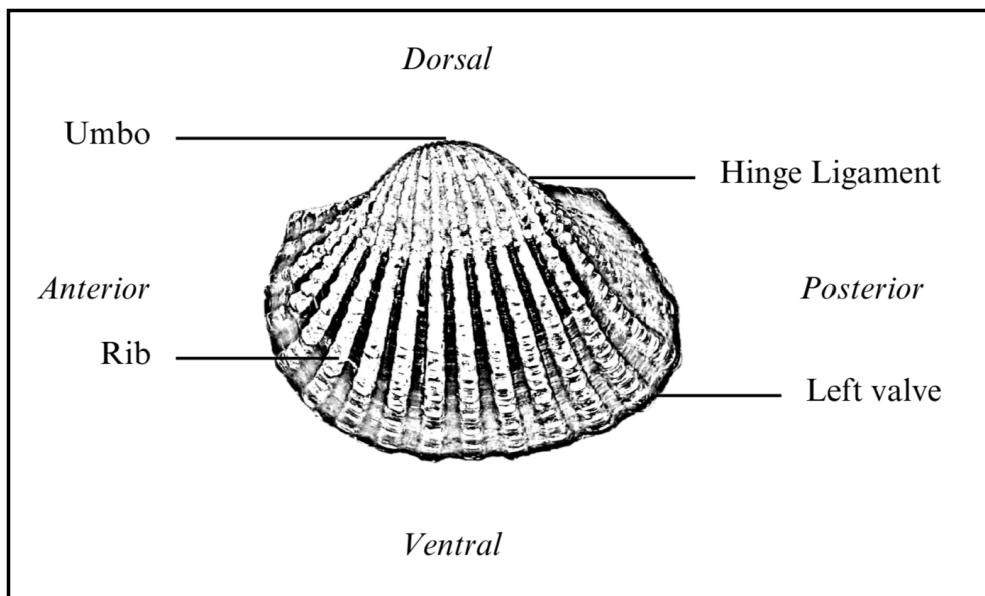

Figure 2.1: Diagram of *Tegillarca granosa* Anatomy

<sup>291</sup> *T. granosa* shell is medium-sized, fairly thick, ovate, and convex, with both  
<sup>292</sup> valves being equal in size but asymmetrical from the hinge. The top edge of  
<sup>293</sup> the dorsal margin is straight, while the front is rounded and slopes downward,  
<sup>294</sup> with its back being obliquely rounded with a concave bottom edge. It has a  
<sup>295</sup> narrow diamond-shaped ligament near the hinge with 3-4 dark chevron markings,  
<sup>296</sup> although some may be incomplete. The shell's outer layer, or the periostracum, is

297 smooth and brown with a straight hinge line and 40-68 fine short teeth arranged  
298 in a straight line. The beak, or prosogyrate, curves forward, with the shell having  
299 18–21 raised ribs with blunt nodules and spaces between them. The inner shell is  
300 white with crenulations along the valves' ventral, anterior, and posterior margins.  
301 The posterior adductor scar is elongated and squarish, while the anterior adductor  
302 scar is similar but smaller in size. The mantle covering the bulk of *T. granosa*'s  
303 visceral mass is thin but the edges are thick and muscular. It bears the impression  
304 of the crenulated shell edges. Their foot is large with a ventral grove with no byssus  
305 or thread-like attachment. The *T. granosa*'s soft body is blood red (Narasimham,  
306 1988).

307 *T. granosa* is one of the most well-known marine bivalves given that they are  
308 a protein-rich food, known for their rich flavor, substantial nutritional benefits, a  
309 good source of vitamins, low in fat, and contain a considerable amount of iron,  
310 important in combating anemia (Zha et al., 2022). Blood cockles were collected  
311 by locals inhabiting the brackish mudflats during the low tides for consumption  
312 and sold in the market as a source of livelihood (Miranda & Ferriols, 2023). *T.*  
313 *granosa* is not only valuable for its market and food purposes but also facilitates  
314 an important role in marine ecosystems as a food source for various organisms  
315 like wading birds, intertidal-feeding fish, and crustaceans such as shore crabs and  
316 shrimp (Burdon, Callaway, Elliott, Smith, & Wither, 2014). Blood cockles can act  
317 as sentinel species and a bioindicator of marine pollutants such as heavy metals  
318 (Ishak, Mohamad, Soo, & Hamid, 2016) and polycyclic aromatic hydrocarbons  
319 (PAHs) (Sany et al., 2014). Additionally, cockle shells can be utilized to create a  
320 cost-effective catalyst for biodiesel production by providing calcium oxide (Boey,  
321 Maniam, Hamid, & Ali, 2011).

322 Determining the sex of bivalves is important for three reasons: diversity, en-  
323 vironmental benefits, and economic significance (Breton et al., 2010). Firstly,  
324 with the estimated 25, 000 living species under class Bivalvia, it would be a suit-  
325 able resource to develop a broader understanding of their evolution of the sex  
326 and sex determination mechanism (Breton et al., 2010). Second, studying sex  
327 determination is important since bivalves are utilized as bioindicators of environ-  
328 mental health. This would pave the way for understanding bivalves' life cycle and  
329 population dynamics in determining different factors that affect them (Campos,  
330 Tedesco, Vasconcelos, & Cristobal, 2012). Thirdly, the immediate and practical  
331 reason to unveil the sex determination mechanism is the economic and nutritional  
332 importance of bivalves as a large population of people relies on fish and shellfish  
333 as sources of food and nutrition (Naylor et al., 2000). Additionally, male and  
334 female aquaculture commodities have different growth and economic values. Male  
335 Nile tilapia, for example, grow faster and have lower feed conversion rates than  
336 females, female Kuruma prawns (*Penaeus japonicus*) are generally larger than

<sup>337</sup> males at the time of harvest (Budd, Banh, Domingos, & Jerry, 2015).

<sup>338</sup> Clearly, much more work is required to understand the mechanisms under-  
<sup>339</sup> lying sexual dimorphism in bivalves, specifically *T. granosa*. Just like the other  
<sup>340</sup> aquaculture commodities, sex affects not just reproduction but it can affect mar-  
<sup>341</sup> ket preference and underlying economic value, making the determination of sex  
<sup>342</sup> important for meeting consumer demands. These are the increasing significance  
<sup>343</sup> of the *T. granosa* despite the lack of reviewed articles in the Philippines.

## <sup>344</sup> **2.2 Current Methods of Sex Identification in *Tegillarca granosa***

<sup>345</sup>

<sup>346</sup> The current sex identification methods in *Tegillarca granosa* range from invasive  
<sup>347</sup> histological techniques to less invasive methodologies like temperature-induced  
<sup>348</sup> spawning. Each approach comes with its pros and cons regarding accuracy, feasi-  
<sup>349</sup> bility, and impact on natural populations.

<sup>350</sup> Induced spawning and larval rearing are considered the less invasive techniques  
<sup>351</sup> used to study *Tegillarca granosa*. In the Philippines, limited research has been  
<sup>352</sup> done on the *Tegillarca granosa* (Linnaeus, 1758), and this study, titled Initial At-  
<sup>353</sup> tempts on Spawning and Larval Rearing of the Blood Cockle, *Tegillarca granosa*  
<sup>354</sup> in the Philippines, is conducted by Denise Vergara Miranda and Victor Marco  
<sup>355</sup> Emmanuel Nuestro Ferriols (2023). The researchers conducted experiments on  
<sup>356</sup> induced spawning and larval rearing, discovering that the eggs of female *T. gra-*  
<sup>357</sup> *nosa* were salmon pink, while the sperm released by males looked milky. After  
<sup>358</sup> spawning, the researchers successfully generated 6, 531, 000 fertilized eggs.

<sup>359</sup> They highlighted the importance of *T. granosa* and other anadarinids as a  
<sup>360</sup> food source that was established worldwide, especially in Malaysia and Korea.  
<sup>361</sup> However, in the Philippines, the bivalve aquaculture of the clam species is still  
<sup>362</sup> limited. The experiment which focuses on the culture and rearing of *T. granosa*  
<sup>363</sup> was attempted by subjecting the wild broodstocks to a series of temperature fluc-  
<sup>364</sup> tuations to induce the spawning of gametes. This is currently the most natural  
<sup>365</sup> and least invasive method for bivalves (Aji, 2011). The study of Miranda and  
<sup>366</sup> Ferriols aimed to pave the way to the sustainable production of *T. granosa* seeds  
<sup>367</sup> for aquaculture production and stock enhancement despite the scarcity of docu-  
<sup>368</sup> mented hatchery culture of *T. granosa* from larvae to adults that is available in  
<sup>369</sup> the Philippines.

<sup>370</sup> In the study entitled "The earliest example of sexual dimorphism in bivalves —

371 evidence from the astartid *Nicanella* (Lower Jurassic, southern Germany)," the  
372 researchers utilized Principal Component Analysis and Fourier Analysis as a non-  
373 invasive method that investigates sexual expression in the *Nicanella rakoveci*. In  
374 the study, researchers discovered that the bivalves with crenulations were found to  
375 have a different shell shape, which made them more inflated than those without  
376 crenulations. This suggests that when they became females, they adapted to  
377 hold more eggs rather than for protection from predators as previously thought.  
378 The formation of crenulations is likely part of the genetic process that controls  
379 both the sex change and the changes in shell structure (Karapunar et al., 2021).  
380 Overall, the findings demonstrate that the genetic mechanisms for sex change and  
381 shell morphology in bivalves existed as early as the Early Jurassic, contributing  
382 to our understanding of bivalve diversity and evolution. Thus, the researchers  
383 concluded that crenulations serve as a morphological marker for identifying the  
384 sex and reproductive stage of these bivalves (Karapunar et al., 2021).

385 On the other hand, invasive techniques such as histological analysis offer a  
386 more thorough but harmful method for determining the sex of *T. granosa*. A  
387 study on the Spawning Period of Blood Cockle *Tegillarca granosa* (Linnaeus,  
388 1758) in Myeik Coastal. 240 blood cockle samples were examined for sex and  
389 gonad maturity stages using histological examination, with shell lengths ranging  
390 from 26-35mm and shell weights from 8.1-33g. For histological analysis, the whole  
391 soft tissues were removed from the shell and the flesh containing most parts of  
392 the gonads was fixed in formalin, dehydrated in an upgraded series of ethanol,  
393 and cleared in xylene. This invasive method allows for precise identification of  
394 the gonadal maturation stages based on the cellular and structural changes in the  
395 gonads.

396 The classification of the gonad stages used was by Yurimoto et al. (2014).  
397 There are five maturation stages of gonadal development: immature (Stage I),  
398 developing (Stage II), mature (Stage III), spawning (Stage IV), and spent (Stage  
399 V) stages. The sex of the *T. granosa* was confirmed by the color of the gonad and  
400 by conducting a histological examination of the gonads. During the immature  
401 stage, sex determination was indistinguishable due to the difficulties of observing  
402 the germ cells. In the developing stage, the spermatocytes and a few spermatids  
403 can be seen for males, and immature oocytes are attached to the tube wall for  
404 the female. In the mature stage, the follicles are full of spermatozoa with their  
405 tails pointing towards the center of the tube for the male, and the female is full  
406 of mature oocytes that are irregular or polygonal in shape with the oval nucleus.  
407 Upon reaching spawning, some spermatozoa are released, causing the empty space  
408 in the follicle wall for males and females. There is a decrease in the number of  
409 mature oocytes and it exhibits nuclear disappearance due to the breakdown of  
410 the germinal vesicle. Lastly, the spent stage is where the genital tube is deformed

411 and devoid of spermatocytes which have completely spawned. In the female, the  
412 genital tube is deformed and degenerated, making it empty. The morphology  
413 of the cockle gonad shows that the area of the gonad increases according to the  
414 increased levels of gonad maturity. The coloration of the gonad tissue layer in the  
415 blood cockle varies from orange-red to pale orange in females and from white to  
416 grayish-white in males for different maturity stages (May et al., 2021).

417 Although the histological examination is the most reliable method for obtain-  
418 ing accurate information on the reproductive biology and sex determination of  
419 *T. granosa*, it has limitations. Given its invasive nature, this approach requires  
420 the dissection and destruction of specimens, making it unsuitable for continuous  
421 monitoring and conservation efforts. Moreover, the current understanding of sex  
422 determination in bivalves and mollusks is poor, and no chromosomes that can  
423 be differentiated based on their morphology have been discovered (Afiati, 2007).  
424 There exists a study that can provide insight into the sex-determining factor in  
425 bivalves but *N. schoberi* is more difficult to analyze concerning potential sexual  
426 dimorphism. Thickening the edges of the shell increases its inflation, which means  
427 the shell can hold more space inside. This extra space helps protandrous females  
428 accommodate more eggs.

## 429 **2.3 Machine Learning and Deep Learning in Bi- 430 ological Studies**

431 Machine learning has the potential to improve the quality of life of human beings  
432 and has a wide range of applications in terms of research and development. The  
433 term machine learning refers to the invention and algorithm evaluation that en-  
434 ables pattern recognition, classification, and prediction based on models generated  
435 from available data (Tarcă, Carey, Chen, Romero, & Drăghici, 2007). The study  
436 of machine learning methods has advanced in the last several years, including bio-  
437 logical studies. In biological studies, machine learning has been used for discovery  
438 and prediction. This section will explore existing machine learning studies that  
439 are applied in biological sciences, highlighting the identification of sex in shells,  
440 bivalves, and mollusks.

441 **2.3.1 Deep Learning for Phenotype Classification in Ark  
442 Shells**

443 In the study, the researchers utilized three (3) convolutional neural network (CNN)  
444 models: the Visual Geometry Group Network (VGGnet), the Inception Residual  
445 Network (ResNet), and the SqueezeNet (Kim, Yang, Cha, Jung, & Kim, 2024).  
446 These deep learning models are utilized for the ark shells, namely *Anadara kagoshimensis*,  
447 *Tegillarca granosa*, and *Anadara broughtonii*, to identify the phenotype  
448 classification.

449 The researchers classified the ark shells based on radial rib count where they  
450 investigated the difference in the number of radial ribs between three species and  
451 were counted. Their CNN-based model that classifies images of three ark shells  
452 can provide a theoretical basis for bivalve classification and enable the tracking of  
453 the entire production process of ark shells from catching to selling with the support  
454 of big data, which is useful for improving food safety, production efficiency, and  
455 economic benefits (Kim et al., 2024).

456 **2.3.2 Geometric Morphometrics and Machine Learning for  
457 Species Delimitation**

458 In *Geometric morphometrics and machine learning challenge currently accepted*  
459 *species limits of the land snail Placostylus (Pulmonata: Bothriembryontidae)* on  
460 *the Isle of Pines, New Caledonia*, the shell size was quantified using centroid size  
461 from the Procrustes analysis, and both the shape and size information were used in  
462 training the machine learning model. Their study concluded that the researchers  
463 support utilizing both methods: supervised and unsupervised machine learning,  
464 rather than choosing either of them individually. In general, their research con-  
465 tributes to the growing number of studies that have combined geometric mor-  
466 phometrics with the aid of machine learning, which is helpful in biological innovation  
467 and breakthrough (Quenu, Trewick, Brescia, & Morgan-Richards, 2020).

468 **2.3.3 Contour Analysis in Mollusc Shells Using Machine  
469 Learning**

470 Tuset et al. (2020), in their study, *Recognising mollusc shell contours with enlarged*  
471 *spines: Wavelet vs Elliptic Fourier analyses*, mentioned that gastropod shells have  
472 large spines and sharp shapes that differ based on environmental, taxonomic, and

473 evolutionary influences. The researchers stated that classic morphometric meth-  
474 ods may not accurately depict morphological features of the shell, especially when  
475 using the angular decomposition of the contour. The current research examined  
476 and compared the robustness of the contour analysis using wavelet transformed  
477 and Elliptic Fourier descriptors for gastropod shells with enlarged spines. For  
478 that, the researchers analyzed two geographically and ecologically separated pop-  
479 ulations of *Bolinus brandaris* from the NW Mediterranean Sea. Results showed  
480 that contour analysis of gastropod shells with enlarged spines can be analyzed  
481 using both methodologies, but the wavelet analysis provided better local discrim-  
482 ination. From an ecological perspective, shells with various sizes of spines in both  
483 areas indicate the broad adaptability of the species.

#### 484 2.3.4 Machine Learning for Shape Analysis of Marine Or- 485 ganisms

486 In the study of Lishchenko and Jones (2021), titled *Application of Shape Analyses*  
487 to *Recording Structures of Marine Organisms for Stock Discrimination and Taxo-*  
488 *nomic Purposes*, they utilized geometric morphometrics (GM) as an approach to  
489 the traditional method of collecting linear measurements with the application of  
490 multivariate statistical methods and outline analysis in recording the structures  
491 of marine organisms. The main taxonomic categories (mollusks, teleost fish, and  
492 elasmobranchs) with their hard bodies have been used as an indication of age and  
493 a determinable time-scale and structure continue to go through life (Arkhipkin,  
494 2005; Kerr & Campana, 2014). This study has explored variations in the mor-  
495 phometry of recording structures in stock discrimination and systematics. The  
496 researchers utilized the principal component analysis rather than the traditional  
497 approach, which helps simplify the data without losing important information.  
498 They utilized landmark-based geometric morphometrics, which has three differ-  
499 ent types, namely: discrete juxtaposition of tissue, maxima or curvature, or other  
500 morphogenetic processes, and lastly, the extremal points are constructed land-  
501 marks.

502 Generalized Procrustes Analysis (GPA) is a common superimposition tech-  
503 nique in landmark-based geometric morphometrics that aligns landmarks via  
504 translation, scaling, and rotation to eliminate non-shape deviations (Zelditch,  
505 Swiderski, & Sheets, 2004). However, there is a limit to the amount of smooth  
506 areas that may be captured, and it is possible to overlook significant shape details.  
507 Utilization of the semi-landmarks enhanced the shape description (Adams, Rohlf,  
508 & Slice, 2004). The researchers observed that using an outline-based approach  
509 would be more effective than using a landmark-based approach.

510 Another approach is the Fourier analysis which is a curve-fitting approach  
511 commonly used due to its well-known mathematical background and how general  
512 functions can be decomposed into trigonometric or exponential functions with  
513 definite frequencies. It has two main approaches, namely: Polar Transform (PT)  
514 in which it expresses the outline using equally spaced radii, and Elliptical Fourier  
515 Analysis (EFA) which separately analyzes the x and y coordinates of the shape.  
516 The PT works for simple rounded outlines and has the tendency to miss details  
517 in more complex shapes, unlike the EFA which can handle complex, convoluted  
518 outlines (Zahn & Roskies, 1972; Doering & Ludwig, 1990; Ponton, 2006). Many  
519 researchers view EFA as the most effective Fourier method for providing a compre-  
520 hensive and detailed description of recording structures (Mérigot, Letourneau, &  
521 Lecomte-Finiger, 2007; Ferguson, Ward, & Gillanders, 2011; Leguá, Plaza, Pérez,  
522 & Arkhipkin, 2013; Mahé et al., 2016).

523 Landmark-based methods used in the study showed that there are detectable  
524 differences between male and female octopuses. However, the accuracy of deter-  
525 mining sex based on these differences was low, similar to the results obtained  
526 with traditional morphometric techniques. The study involved a relatively small  
527 sample size of 160 individuals, and the structure being analyzed (the stylet, or  
528 internalized shell) varies significantly between individuals. Although the results  
529 aligned with findings from other studies that attempted to identify gender differ-  
530 ences in cephalopods, the researchers concluded that the approach might not be  
531 accurate enough for reliable sex determination.

### 532 **2.3.5 Deep Learning for Landmark-Free Morphological Fea- 533 ture Extraction**

534 In another study, *a deep learning approach for morphological feature extraction*  
535 *based on variational auto-encoder: an application to mandible shape*, the Morpho-  
536 VAE machine learning approach was used to conduct a landmark-free shape ana-  
537 lysis. Morpho-Vae reduces dimensions by concentrating on morphological features  
538 that distinguish data with different labels using an image-based deep learning  
539 framework that combines unsupervised and supervised machine learning. After  
540 utilizing the method in primate mandible images, the morphological features re-  
541 veal the characteristics to which family they belonged. Based on the result, the  
542 method applied provides a versatile and promising tool for evaluating a wide range  
543 of image data of biological shapes including those missing segments.

### **544 2.3.6 Machine Learning for Sex Differentiation in Abalone**

545 In the study, *Towards Abalone Differentiation Through Machine Learning*, re-  
546 searchers identified a problem in abalone farming which is having to identify the  
547 sex of abalone to apply measures for its growth or preservation. The researchers  
548 classified abalone sex using machine learning. Researchers trained the machine  
549 to classify different types of classes which are male, female, and immature. The  
550 results demonstrated the effectiveness of utilizing linear classifiers for this task.

551 Similarly, in the study, *Data scaling performance on various machine learning*  
552 *algorithms to identify abalone sex*, the researchers of the University of India (2022)  
553 focused on the data scaling performance of various machine learning algorithms to  
554 identify the abalone sex, specifically using min-max normalization and zero-mean  
555 standardization. The different machine learning algorithms are the Supervised  
556 Vector Machine (SVM), Random Forest, Naive Bayesian, and Decision Tree. Their  
557 study aims to utilize machine learning in terms of identifying the trends and  
558 distribution patterns in the abalone dataset. Eight features of the abalone dataset  
559 (length, diameter, height, whole weight, shucked weight, viscera weight, shell  
560 weight, ring) were used to determine the three sexes of Abalone. Their data has  
561 been grouped based on sex which are Female, Male, and Infant. They utilized  
562 the Synthetic Minority Oversampling Technique (SMOTE) in data balancing for  
563 the preprocessing of the data. Followed by data scaling or normalization where  
564 it converts numeric values in a data set to a general scale without distorting  
565 differences in the range of values. Then they classified by splitting the data into  
566 training and testing sets (Arifin, Ariawan, Rosalia, Lukman, & Tufailah, 2021).

567 The study found that Naive Bayes consistently performed better than other al-  
568 gorithms. However, when applied to both min-max and zero-mean normalization,  
569 the average accuracies of the algorithms were as follows: Random Forest (62.37%),  
570 SVM with RBF kernel (59.49%), Decision Tree (57.20%), SVM with linear ker-  
571 nel (56.59%), and Naive Bayes (53.39%). Despite the performance decrease with  
572 normalization, Random Forest achieved the highest overall metrics, including an  
573 average balanced accuracy of 74.87%, sensitivity of 66.43%, and specificity of  
574 83.31%. Liu et al. concluded that Random Forest is highly accurate because it  
575 can handle large, complex datasets, run processes in parallel using multiple trees,  
576 and select the most relevant features to enhance model performance (Arifin et al.,  
577 2021).

578 **2.3.7 Machine Learning for Geographical Traceability in**  
579 **Bivalves**

580 In the study, *BivalveNet: A hybrid deep neural network for common cockle (*Cerastoderma edule*) geographical traceability based on shell image analysis*, the re-  
581 searchers incorporated computer vision and machine learning technologies for an  
582 efficient determination of blood cockle harvesting origin based on the shell geomet-  
583 ric and morphometric analysis. It aims to improve the traceability methodologies  
584 in these organisms and its potential as a reliable traceability tool. Thirty *Cerasto-*  
585 *derma edule* samples were collected along the five locations on the Atlantic West  
586 and South Portuguese coast with individual images processed using lazy snapping  
587 segmentation, spectro-textural-morphological phenotype extraction, and feature  
588 selection through hybrid Principal Component Analysis and Neighborhood Com-  
589 ponent Analysis (Concepcion, Guillermo, Tanner, Fonseca, & Duarte, 2023).

591 The researchers developed a non-invasive image-based traceability technique,  
592 an alternative to the chemical and biochemical analysis of the bivalves. It was  
593 able to incorporate machine learning methods to promote lesser human interven-  
594 tion. The researchers discovered that BivalveNet emerged as the superior model  
595 for bivalves with 96.91% accuracy which is comparable to the accuracy of the  
596 destructive methods with 97% and 97.2% accuracy rates. The result of the study  
597 aided the researchers in concluding that there is a possibility of on-site evalua-  
598 tion of the bivalve through the implementation of a mobile app that would allow  
599 the public and official entities to obtain information regarding the provenance of  
600 seafood products' traceability because of its non-invasive and image-based aspects  
601 (Concepcion et al., 2023).

602 *Tegillarca granosa* is known for having no sexual dimorphism. However, through  
603 several related studies, the researchers can apply how family shells of *Tegillarca*  
604 *granosa* have been identified based on its morphological and morphometric char-  
605 acteristics and the methods used in machine learning in identifying its sex.

606 **2.4 Limitations on Sex Identification in *Tegillarca***  
607 ***granosa***

608 To date, no distinction has been made between the male and female *T. granosa*  
609 in sexing methodology. In cockle aquaculture without clearly apparent sexual  
610 dimorphism, sexing can be performed using invasive methods such as chemical  
611 stimulation, dissection, and gonad-stripping. Induced spawning, specifically tem-

612 perature shock, is the most natural and least invasive method for bivalves (Aji,  
613 2011). However, the method (Wong & Lim, 2018) of immersing cockles in water  
614 from hot to cold with a specific temperature requires deliberate and careful ma-  
615 nipulation of the temperature over a specific period and would require constant  
616 management and monitoring.

617 Recent studies involved non-invasive methods, with a specific emphasis on  
618 morphological characteristics as indicators of sex differentiation. However, Tat-  
619 suya Yurimoto et al. (2014) stated that the existing methods for determining  
620 the sex of bivalves and mollusks in general are somewhat limited (Afiati, 2007).  
621 At present, there is no recorded evidence of sexual dimorphism in *Tegillarca gra-*  
622 *nosa*. Gonochoristic is the classification given to *Tegillarca granosa* (Lee, 1997).  
623 However, Lee et al. (2012) reported that the sex ratio varied with shell length,  
624 suggesting that sex might alter.

625 Hermaphrodites can exhibit either sequential (asynchronous) or simultaneous  
626 (synchronous or functional) characteristics. Sequential hermaphrodites switch  
627 genders after being male or female for one or multiple yearly cycles. (Heller,  
628 1993; Gosling, 2004; Collin, 2013). Sex change and consecutive hermaphroditism  
629 have been observed in different bivalve species, including Ostreidae, Pectinidae,  
630 Veneridae, and Patellidae. However, macroscopically differentiating bivalve sex is  
631 challenging. The only way it may be identified is through histological analysis of  
632 gonad remains but to do so there is an act of killing the organism (Coe, 1943;  
633 Gosling, 2004). Verification of sex change in bivalves to classify whether male or  
634 female while they are alive is challenging since they need to be re-confirmed and  
635 re-evaluated to be the same individual after a year.

636 Lee et al. (2012) found out that *T. granosa*, a species in Arcidae, has been  
637 discovered to be a sequential hermaphrodite, with the sex ratio changing with an  
638 increase in the shell size. In bivalves, sex changes usually happen when the gonad  
639 is not differentiated between spawning seasons (Thompson, Newell, Kennedy, &  
640 Mann, 1996). But in *T. granosa*, after the spawning season, sex changes during  
641 its inactive phase. Results showed a 15.1% sex change ratio, with males having  
642 a higher sex change ratio (21.2%) than females (6.2%). The 1+ year class had a  
643 higher ratio (17.8%) than the 2+ year class (12.1%). Thus, this study indicates  
644 that *T. granosa* is a sequential hermaphrodite. The results of the study demon-  
645 strated that the bivalve's age affects the sex ratio and degree of sex change, but  
646 additional in-depth investigation is required to determine the role that genetic  
647 and environmental factors play in these changes.

648 No literature in the study of mollusks specifically addresses the machine learn-  
649 ing algorithm used to determine the sex of *T. granosa* bivalves in various mod-  
650 els. Nevertheless, various techniques such as shape analysis, morphometric ana-

651 lysis, Wavelet, and Fourier analysis, as well as different deep learning models like  
652 VGNet, ResNet, and SqueezeNet in CNN networks, are utilized for phenotype  
653 classification, while different machine learning algorithms could serve as the foun-  
654 dation for this research project.

## 655 **2.5 Synthesis of the Study**

656 This section of the paper summarizes the technologies used in the different studies  
657 related to the pursuit of the study entitled, Morphometric-Based Non-Invasive Sex  
658 Identification of Blood Cockles *Tegillarca granosa* (Linnaeus, 1758).

Author	Technology / Method Used	Description of Problem	Pros	Cons
D. V. Miranda and V. M. E. N. Ferriols	Temperature shock	No recent studies are available on the production and rearing of <i>T. granosa</i> in the Philippines.	Employed less invasive techniques which minimize the stress in <i>T. granosa</i> and can lead to better survival rates.	Time-consuming as the entire process from fertilization to the spat stage took 120 days.
Karapunar, Baran and Werner, W. and Fürsich, F. T. and Nützel, A.	Morphometric analysis, microscope imaging, principal component analysis (PCA), and Fourier shape analysis	To address the observed shell dimorphism in the Early Jurassic bivalve <i>Nicanella rakoveci</i> , namely the presence or lack of crenulations on the ventral shell margin, and whether these variations represent sexual dimorphism and sequential hermaphroditism.	The methods used reveal significant morphological differences with regard to sexual dimorphism.	There could be misinterpretation of the shape differences of bivalves due to the constraints and resolution of technologies used.
K. May and C. Maung and E. Phyu and N. Tun	Histological examination	The need to understand the reproductive period of <i>T. granosa</i> in Myeik to ensure sustainable aquaculture and to prevent overexploitation.	Method used allows for accurate sex identification based on the histological characteristics and color of the gonads.	Invasive technique used to determine the sex of <i>T. granosa</i> through gonad histological analysis.
E. Kim and S.-M. Yang and J.-E. Cha and D.-H. Jung and H.-Y. Kim	Convolutional neural network (CNN) models, VGGNet, Inception-ResNet, SqueezeNet	Traditional methods of recognizing and classifying ark shell species based on shell traits are time-consuming and inaccurate.	Automated classification of the three ark shells using a deep learning model obtained an accuracy of 92.4%.	Challenges may arise with certain ark shells that share similar morphology.
Mathieu Quemu and S. A. Trewick and F. Brescia and M. Morgan-Richards	Neural network analysis (supervised learning) and Gaussian mixture models (unsupervised learning)	To determine whether the shape and size of the snail's shells can distinguish between two <i>Placostylus</i> species, particularly in groups that appear to be hybrids.	Combining geometric morphometrics and machine learning effectively answers biological issues, providing insights into species classification and possible hybridization.	Difficulty classifying intermediate phenotypes, with potential for overfitting and misclassification in both learning methods.
V. M. Tusset and E. Galimany and A. Farrés and E. Marco-Herrero and J. L. Otero-Ferrer and A. Lombarte and M. Ramón	Wavelet functions and Elliptic Fourier descriptors	Addresses the difficulty of accurately defining phenotypic diversity in gastropod shells.	Advanced contour analysis methods allow accurate differentiation of gastropod shell forms.	Cannot clarify the causes of phenotypic variation in the two populations studied.
Fedor Lishchenko and Jones, J. B.	Landmark- and outline-based Geometric Morphometric methods	To address difficulties in differentiating between stocks of marine organisms to prevent misidentification that could affect conservation and management.	Shape analysis improves taxonomic classification precision and offers close distinction between related species or organisms.	Landmark-based methods can be sensitive to landmark placement.
M. Tsutsumi and N. Saito and D. Koyabu and C. Furusawa	Morphological regulated variational AutoEncoder (Morpho-VAE)	The need for reliable, landmark-free methods, such as a modified variational autoencoder, to extract and decipher complex shapes from image data.	Employs dimension reduction and feature extraction, making it a user-friendly tool for biology non-experts.	Limited sample size in certain families presented challenges.
Barrera-Hernandez, R. and Barrera-Soto, V. and Martinez-Rodriguez, J. L. and Ríos-Alvarado, A. B. and Ortiz-Rodriguez, F.	Machine learning algorithms	Identifying the sex of abalones is challenging for producers applying specific growth or preservation strategies.	Machine learning algorithms accurately classify abalone sex into three categories: male, female, and immature.	Selected features may not fully capture the complexity of abalone morphology.
Concepcion, R. and Guillermo, M. and Tanner, S. E. and Fonseca, V. and Duarte, B.	EfficientNet-Bo, ResNet101, MobileNetV2, InceptionV3	Addresses the difficulty of accurately tracing bivalve harvesting origins using computer vision and machine learning algorithms to enhance seafood traceability and combat food fraud.	Non-invasive, image-based tools for bivalve traceability provide faster, cheaper, and equally accurate alternatives to traditional chemical analysis methods.	Small sample size (only 30 cockles) limits model reliability.

Table 2.1: Comparison of the Methods Used in Bivalves Studies

659       Recent developments and breakthroughs in machine learning offer hopeful  
660       solutions for biological issues. Research findings indicate that various machine  
661       learning techniques such as CNNs, geometric morphometrics, and deep learning  
662       models. They are deemed effective for identifying phenotypes and determining  
663       the gender of various aquaculture commodities, such as mollusks and abalones.  
664       These techniques provide a starting point for creating new, non-invasive ways to  
665       differentiate male and female *T. granosa*, potentially addressing the drawbacks of  
666       manual and invasive methods. Thus, machine learning to examine morphological  
667       and morphometric features may streamline the process of sex identification.

668       Nevertheless, the use of machine learning to determine the sex of *T. granosa*  
669       has not been fully explored. It lacks up-to-date and significant related literature  
670       on using machine learning to identify sex in *T. granosa*, particularly given the  
671       species' possible sequential hermaphroditism and lack of obvious external sexual  
672       distinctions.

# <sup>673</sup> Chapter 3

## <sup>674</sup> Research Methodology

<sup>675</sup> This chapter discussed the materials and methods employed in the study, focusing  
<sup>676</sup> on the development requirements, as well as the software and programming  
<sup>677</sup> languages utilized. It also detailed the overall workflow in conducting the study,  
<sup>678</sup> Morphometric-Based Non-Invasive Sex Identification of Blood Cockles *Tegillarca*  
<sup>679</sup> *granosa* (Linnaeus), 1758) using machine learning and deep learning technologies.

<sup>680</sup> Dr. Victor Emmanuel Ferriols, the director of the Institute of Aquaculture,  
<sup>681</sup> oversaw the overall workflow and conduct of the experiment. The researchers were  
<sup>682</sup> also guided by research associates LC Mae Gasit and Allena Esther Artera. Con-  
<sup>683</sup> sequently, the entire dataset collection process was conducted at the University of  
<sup>684</sup> the Philippines Visayas hatchery facility.

<sup>685</sup> The methodology consisted of eight parts: (1) Sample Collection, (2) Ethical  
<sup>686</sup> Considerations, (3) Creating *T.granosa* Dataset, (4) Morphological Characteris-  
<sup>687</sup> tics Collection (5) Image Acquisition and Pre-processing, (6) Hardware and Soft-  
<sup>688</sup> ware Configuration,(7) Morphometric Characteristics Evaluation Using Machine  
<sup>689</sup> Learning, and (8) Morphological Characteristics Evaluation Using Deep Learning

### <sup>690</sup> 3.1 Sample Collection

<sup>691</sup> The collection of *T. granosa* samples used in this study was part of an ongoing  
<sup>692</sup> research project by UPV DOST-PCAARRD titled "Establishment of the Center  
<sup>693</sup> for Mollusc Research and Development: Development of Spawning and Hatchery  
<sup>694</sup> Techniques for the Blood Cockle (*Anadara granosa*) for Sustainable Aquaculture."  
<sup>695</sup> A total of 271 samples were provided for this study to classify the sex of *T. granosa*.

696 The samples, ranging in size from 34 to 61 mm, were sourced from the coastal area  
697 of Zaraga, Iloilo, and fish markets in Ivisan, Capiz, Philippines (see Figure 3.1).

698 The research and experimentation were conducted at the University of the  
699 Philippines Visayas hatchery facility in Miagao, Iloilo, where the samples were  
700 maintained in 200 L fiberglass-reinforced plastic (FRP) tanks containing filtered  
701 seawater with 35 ppt salinity (Miranda & Ferriols, 2023).

702 As part of the data collection process, the researchers utilized induced spawning  
703 and dissection to classify the sex of the samples. Induced spawning through  
704 temperature fluctuations was the most natural and least invasive method for bi-  
705 valves compared to other approaches (Aji, 2011). However, since not all samples  
706 exhibited gamete release, the researchers also performed dissections, assisted by  
707 hatchery staff, to expedite data collection. The sex of the dissected samples was  
708 identified based on the coloration of gonad tissue, which varies according to sex  
709 and maturity stage. Females exhibited orange-red to pale orange gonads, while  
710 males displayed white to grayish-white gonads (May et al., 2021).

711 The methods used for data collection were considered noninvasive, particularly  
712 given that *T. granosa* are oxygen regulators well adapted to tidal exposure and  
713 hypoxia (Davenport & Wong, 1986).

Figure 3.1: Male and Female *Tegillarca granosa* shells

## **714 3.2 Ethical Considerations**

715 The ongoing research project titled "Establishment of the Center for Mollusc Re-  
716 search and Development: Development of Spawning and Hatchery Techniques for  
717 the Blood Cockle (*Anadara granosa*) for Sustainable Aquaculture"—from which  
718 the samples used in this study were obtained—was reviewed and approved by the  
719 Institutional Animal Care and Use Committee (IACUC) of the University of the  
720 Philippines Visayas.

## **721 3.3 Creating *T. granosa* Dataset**

722 The experiment began with the collection of preliminary observations from 100 *T.*  
723 *granosa* samples. For the actual experimentation, the researchers collected the full  
724 dataset in batches until a total sample size of 271 *T. granosa* was reached. Lin-  
725 ear measurements—including width, height, length, rib count, hinge line length,  
726 and the distance between the umbos—were recorded and organized into a CSV  
727 file. This dataset served as the foundation for training and testing machine learn-  
728 ing models, as well as for establishing a baseline for the Convolutional Neural  
729 Networks.

730 Images of each sample were captured and saved in JPG format using a stan-  
731 dardized file naming convention that included the sample's sex, the shell's ori-  
732 entation or view, and its corresponding number out of the 271 total samples. File  
733 names for female *T. granosa* samples began with "0", while those for male sam-  
734 ples began with "1". Each file name also included one of the six captured views:  
735 (1) dorsal, (2) ventral, (3) anterior, (4) posterior, (5) left lateral, and (6) right  
736 lateral (refer to Figure 3.2), followed by a unique sample number. For exam-  
737 ple, "010001" denoted the first female sample taken from the dorsal view, while  
738 "110001" represented the first male sample from the same view. This naming  
739 convention was implemented to prevent data leakage and ensure accurate labeling  
740 of images according to their respective samples.

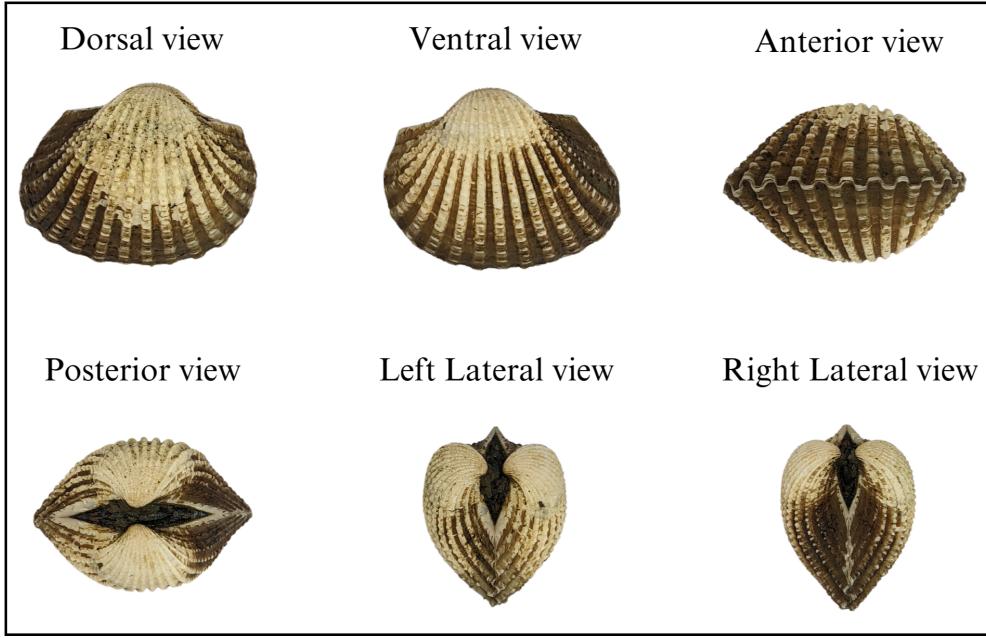

Figure 3.2: Different Views of the *T. granosa* Shell Captured

### <sup>741</sup> 3.4 Morphological and Morphometric Characteristics Collection

<sup>742</sup> Morphology refers to biological form and is one of the most visually recognizable phenotypes across all organisms (Tsutsumi, Saito, Koyabu, & Furusawa, 2023).  
<sup>743</sup> In this study, morphological characteristics describe the structural features of *T. granosa*, focusing on measurable attributes such as shape, size, and color.  
<sup>744</sup> Morphometric characteristics, on the other hand, refer to specific quantifiable features of *T. granosa*, including length, width, height, hinge line length, distance between the umbos, and rib count. As stated by the researchers, quantifying and characterizing these traits is essential for understanding and visualizing variations in *T. granosa* morphology.

<sup>751</sup> The researchers measured the height, width, and length of *T. granosa* using a Vernier caliper with a precision of up to 0.01 mm. Refer to Figure 3.3 for the corresponding measurement diagram. Length (A) refers to the distance from the anterior to the posterior of the shell. Width (B) is defined as the widest span across the shell from the left to the right valve. Height (C) measures the distance from the base to the apex of the shell. In addition, the hinge line length (D) near the hinge and the distance between the umbos (E) were recorded.

<sup>752</sup> Reament and Kennedy (1998) emphasized that including rib count as supple-

mentary information can enhance identification accuracy. Following this insight, the researchers also recorded the rib count for both male and female *T. granosa*, adjusting the values by calculating ratios to account for natural size variation among specimens.

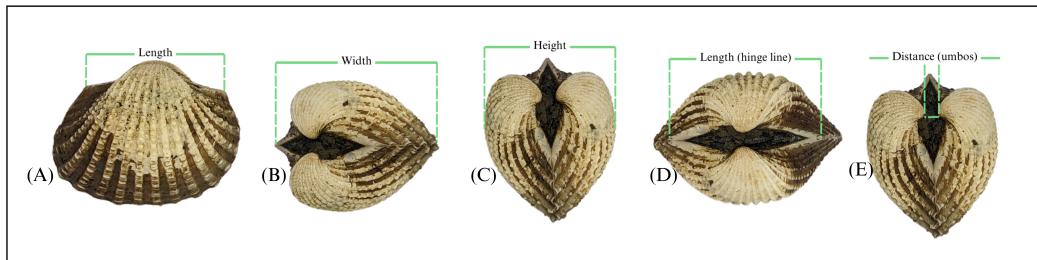

Figure 3.3: Linear Measurements of *Tegillarca granosa* shell.

### 3.5 Image Acquisition and Data Gathering

This study comprised 144 male and 127 female *T. granosa* samples, resulting in a total of 1,626 images captured from various angles. To ensure consistency during image acquisition, the researchers constructed a box-like structure with a white background to control the imaging environment. This setup allowed for uniform image captures by fixing the camera at a consistent angle directly above the *T. granosa*. A ring light was positioned in front of the box to enhance image quality, eliminate shadows, and ensure clarity of the samples throughout the image acquisition process.

The images were captured using a Google Pixel 3 XL smartphone, which features a resolution of  $2960 \times 1440$  pixels and a 12.2 MP camera ( $4032 \times 3024$  pixels). Additional camera specifications include an f/1.8 aperture, 28mm wide lens,  $\frac{1}{2.55}$ " sensor size, 1.4 $\mu\text{m}$  pixel size, dual-pixel phase detection autofocus (PDAF), and optical image stabilization (OIS) (Concepcion et al., 2023).

Figure 3.4: Image Acquisition Setup for *T. granosa* Samples

### 778 3.6 Hardware and Software Configuration

779 This section of the paper discusses the software, programming languages, and tools  
780 used for sex identification. Data collection, preprocessing, and model training  
781 were conducted on a Windows 11 operating system using an ACER Aspire 3  
782 general-purpose unit (GPU) equipped with an AMD Ryzen 3 7320U CPU with  
783 Radeon Graphics (8 cores) @ 2.395 GHz and 8 GB of RAM. Google Colaboratory  
784 was utilized for collaborative preprocessing, computer vision tasks, and model  
785 training. Image preprocessing was performed using computer vision techniques in  
786 Python, while machine learning and deep learning models were developed using  
787 Python libraries, including Keras. The results of the gathered measurements were  
788 stored and managed using spreadsheet software. GitHub was employed for version  
789 control, documentation, and activity tracking throughout the study.

### 790 3.7 Morphometric Characteristics Evaluation Us- 791 ing Machine Learning

792 This section of the paper discusses the machine learning operations that served  
793 as a baseline prior to implementing more complex deep learning methods for  
794 image classification. The study utilized collected variables including linear mea-  
795 surements—length, width, height, hinge line length, distance between the um-  
796 bos, and rib count—along with derived features used as predictors. These in-  
797 cluded the length-to-width ratio, length-to-height ratio, width-to-height ratio,  
798 umbo distance-to-length ratio, hinge line length-to-length ratio, umbo distance-

<sup>799</sup> to-height ratio, and rib density. The samples were classified by sex, with females  
<sup>800</sup> labeled as 0 and males as 1, which served as the response variable.

### <sup>801</sup> 3.7.1 Data Preprocessing

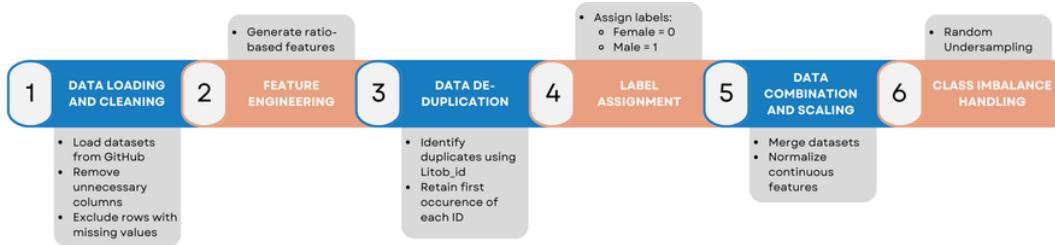

Figure 3.5: Data Preprocessing Pipeline

<sup>802</sup> The preprocessing of the dataset involved several essential steps, carried out  
<sup>803</sup> using Python in Google Colaboratory, in preparation for machine learning analysis  
<sup>804</sup> (see Figure 3.5).

#### <sup>805</sup> *Data Loading and Cleaning*

<sup>806</sup> The process began by loading two separate datasets for male and female *T.  
granosa* directly from GitHub using `pd.read_csv()`. Unnecessary columns were  
<sup>807</sup> removed, and rows containing missing values were excluded using the `dropna()  
808` function to ensure data completeness and reliability.

#### <sup>810</sup> *Feature Engineering*

<sup>811</sup> Additional ratio-based features were generated to augment the existing measurements.  
<sup>812</sup> These included the length-to-width ratio, length-to-height ratio, width-  
<sup>813</sup> to-height ratio, hinge line length-to-length ratio, umbos distance-to-length ratio,  
<sup>814</sup> umbos distance-to-height ratio, and rib density. These derived features aimed to  
<sup>815</sup> emphasize shape characteristics independent of size, improving the models' ability  
<sup>816</sup> to distinguish morphological differences between sexes.

#### <sup>817</sup> *Data De-duplication*

<sup>818</sup> To avoid redundancy and ensure each specimen was uniquely represented, the  
<sup>819</sup> last three digits of each `Litob_id` were used to identify duplicates. Only the first  
<sup>820</sup> occurrence of each unique ID was retained, reducing potential bias caused by  
<sup>821</sup> repeated entries.

822      ***Label Assignment***

823      A new column labeled `Label` was added to both datasets. Female specimens  
824      were assigned a label of 0, and male specimens a label of 1. This column served  
825      as the target variable for classification.

826      ***Data Combination and Scaling***

827      After cleaning and feature engineering, the male and female datasets were  
828      merged into a single DataFrame. The `Litob_id` column was removed post de-  
829      duplication. All continuous numeric features were normalized using `MinMaxScaler`  
830      to scale values to the range [0, 1].

831      Rib count was excluded from normalization because it is a discrete feature with  
832      biologically meaningful bounds. According to best practices in machine learning,  
833      normalizing discrete or categorical features can distort their meaning and is often  
834      unnecessary (Jaiswal, 2024). In this study, rib count was treated as a categorical  
835      attribute due to its biological significance and finite, non-continuous nature.

836      ***Class Imbalance Handling***

837      After normalization, class imbalance was addressed by applying Random Under-  
838      sampling to the male dataset. This technique randomly reduced the number of  
839      male samples to match the number of female samples (127 each), ensuring equal  
840      class representation. By using this approach, model bias was minimized, and the  
841      classification performance became more reliable across both classes.

842      **3.7.2 Machine Learning Models Training**

843      ***Model Selection and Hyperparameter Tuning***

844      To establish a baseline for classification, various models were evaluated: Logis-  
845      tic Regression, K-Nearest Neighbors, Support Vector Machine, Random Forest,  
846      AdaBoost, Extra Trees, and Gradient Boosting. Hyperparameter tuning was con-  
847      ducted using `GridSearchCV`, which systematically identified the optimal settings  
848      for each model to enhance accuracy and performance.

849      ***Cross-Validation***

850      A five-fold cross-validation approach was implemented. The dataset was di-  
851      vided into five subsets, with four used for training and one for testing. This  
852      process was repeated five times, with each fold serving as the test set once. This

853 method ensured that model evaluation was robust and generalizable, minimizing  
854 the bias that may result from a single train-test split. (GeeksforGeeks, 2024)

Figure 3.6: Diagram of k-fold cross-validation with  $k = 5$

### 855 3.7.3 Evaluation Metrics for Machine Learning

856 Evaluating the performance of the binary classification model is important as well  
857 as selecting the appropriate metrics that is based on the requirements of the user.  
858 The performance of the supervised machine learning models will be measured  
859 based on four metrics namely: accuracy, precision, recall, and F1 score.

860 Accuracy (ACC) is the ratio of the overall correctly predicted samples to the  
861 total number of examples in the evaluation dataset (Cui, Pan, Chen, & Zou, 2020).  
862 The overall correctness of the model in predicting male and female blood cockles.  
863 This metric could help in understanding how well the model performs across all  
864 classifications. The formula for the accuracy is:

$$\text{ACC} = \frac{\text{Correctly classified samples}}{\text{All samples}} = \frac{TP + TN}{TP + FP + TN + FN} \quad (3.1)$$

865 Precision (PREC) is the ratio between correctly predicted samples in all samples  
866 that are assigned to the positive class (Cui et al., 2020). This metric promotes fair  
867 representation and prevents the misidentification of blood cockles as it identifies  
868 potential inaccuracies or biases. The formula for precision is:

$$\text{PREC} = \frac{\text{True positive samples}}{\text{Samples assigned to class}} = \frac{TP}{TP + FP} \quad (3.2)$$

869        Recall (REC) is known as the sensitivity or the true positive rate (TPR) which  
 870      is the ratio of the correctly predicted cases from all the samples assigned to the  
 871      actual positive cases (Cui et al., 2020). This metric is the ability of the model to  
 872      correctly identify positive male and female samples. The formula for the recall is:

$$\text{REC} = \frac{\text{True positive samples}}{\text{Samples classified positive}} = \frac{TP}{TP + FN} \quad (3.3)$$

873        F1 score is defined as the mean of the precision and recall in which it penalizes  
 874      the extreme values of either of the two (Cui et al., 2020). The formula for the F1  
 875      is:

$$\text{F1} = \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}} = \frac{2 \times TP}{2 \times TP + FP + FN} \quad (3.4)$$

<sup>876</sup> **Chapter 4**

<sup>877</sup> **Results and Discussions**

<sup>878</sup> This chapter presents the results of the machine learning and deep learning anal-  
<sup>879</sup> yses conducted on the preprocessed dataset. Preprocessing was performed using  
<sup>880</sup> Python in Google Colaboratory. The chapter includes the evaluation of various  
<sup>881</sup> machine learning classifiers, analysis of feature importance, and the application  
<sup>882</sup> of deep learning models for image-based classification. These approaches aim to  
<sup>883</sup> identify key predictors and assess classification performance for sex identification  
<sup>884</sup> in *T. granosa*.

<sup>885</sup> **4.1 Machine Learning Analysis**

<sup>886</sup> **4.1.1 Data Exploration**

<sup>887</sup> Exploratory data analysis was performed to characterize the dataset using visu-  
<sup>888</sup> alizations to understand the patterns and correlations within the data. A corre-  
<sup>889</sup> lation heatmap was created to assess the relationship between the predictors and  
<sup>890</sup> the target variable.

<sup>891</sup> The heatmap (see Figure 4.1) revealed three features most correlated with the  
<sup>892</sup> sex of *T. granosa*: the width-height ratio ( $r = 0.18$ ), the umbos-length ratio ( $r$   
<sup>893</sup> = 0.12), and the distance between the umbos ( $r = 0.12$ ). Each of these features  
<sup>894</sup> demonstrated a weak positive relationship with the target variable.

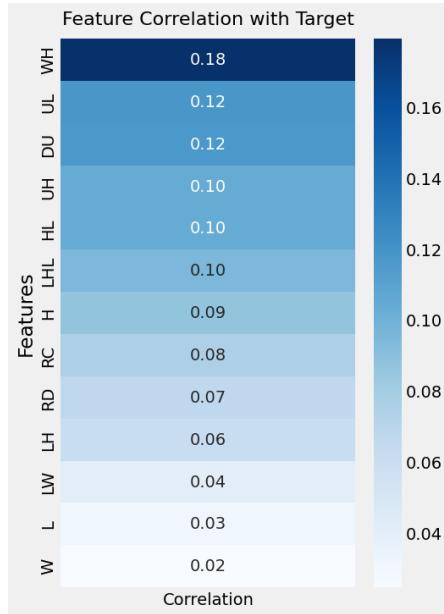

Figure 4.1: Correlation heatmap of morphometric features with the sex of *T. granosa*

<sup>895</sup> **4.1.2 Statistical Analysis**

Variable	p-value
Length	0.334
Width	0.753
Height	0.124
Rib count	0.251
Length (Hinge Line)	0.120
Distance Umbos	0.025
LW_ratio	0.011
LH_ratio	0.490
WH_ratio	0.003
UL_ratio	0.019
HL_ratio	0.079
UH_ratio	0.036
Rib Density	0.181

Table 4.1: Mann-Whitney U Test Results for Sex-Based Feature Comparison

<sup>896</sup> As part of the exploratory data analysis, statistical testing confirmed that the  
<sup>897</sup> dataset did not follow a normal distribution. Consequently, the Mann-Whitney  
<sup>898</sup> U test was applied with a significance level of  $\alpha = 0.05$  to compare male and

899 female samples. Out of thirteen features, five showed statistically significant dif-  
900 ferences. These included: distance between umbos ( $p = 0.025$ ), length-width ratio  
901 ( $p = 0.011$ ), umbos-length ratio ( $p = 0.019$ ), width-height ratio ( $p = 0.003$ ), and  
902 umbos-height ratio ( $p = 0.036$ ).

903 It is important to note that statistical significance does not imply predictive  
904 importance. Therefore, further analysis, such as feature importance evaluation,  
905 was performed to identify the most informative predictors for classification.

#### 906 4.1.3 Feature Importance Analysis

Figure 4.2: Feature Importance Scores Using the Kruskal-Wallis Test

907 Feature importance was assessed using the Kruskal-Wallis test, a non-parametric  
908 method that is suitable for evaluating differences in distributions across groups  
909 when the data does not follow a normal distribution. This approach was chosen  
910 because of the non-normality of the dataset and its robustness in handling con-  
911 tinuous and ordinal data without assuming homogeneity of variances. (Ribeiro,  
912 2024)

913 The analysis showed that the width-to-height ratio (WH\_ratio) had the high-  
914 est importance score, indicating it is the most statistically significant feature for

915 distinguishing the sex of *T. granosa*. Other notable features included the length-  
 916 to-width ratio (LW\_ratio), umbos-to-length ratio (UL\_ratio), and the distance  
 917 between the umbos, all of which contributed significantly to the classification  
 918 task.

#### 919 4.1.4 Performance Evaluation

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Support Vector Machine	58.62	58.62	58.62	58.44
Logistic Regression	57.83	57.83	57.83	57.61
K-Nearest Neighbors	51.18	51.31	51.18	50.77
Extra Trees	60.24	56.98	56.69	56.39
Random Forest	59.07	59.46	59.06	58.74
Gradient Boosting	60.27	60.98	60.27	59.96
AdaBoost	60.63	60.98	60.63	60.39

Table 4.2: Performance Metrics for Models with All 13 Features

920 In table 4.2, the performance of different machine learning models is presented  
 921 using the full set of 13 features from the dataset. AdaBoost emerges as the  
 922 highest-performing model, with an accuracy of 60.63%, precision of 60.98%, recall  
 923 of 60.63%, and an F1-score of 60.39%. These results suggest that AdaBoost is  
 924 particularly effective when utilizing all available features, likely due to its ability  
 925 to combine multiple weak learners into a more robust model.

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Support Vector Machine	63.77	64.47	63.77	63.42
Logistic Regression	63.75	63.87	63.75	63.70
K-Nearest Neighbors	64.16	64.97	64.16	63.75
Extra Trees	62.20	59.69	59.08	58.69
Random Forest	62.96	60.10	59.85	59.54
Gradient Boosting	63.39	64.24	64.16	64.04
AdaBoost	61.02	61.26	61.02	60.82

Table 4.3: Performance Metrics for Models with 5 Features

926 Table 4.3 presents the performance of the same models using only the top 5  
 927 features identified through Kruskal-Wallis feature importance analysis. The top  
 928 5 features selected are distance between the umbos, length-to-width ratio, width-  
 929 to-height ratio, umbos-to-height ratio and umbos-to-length ratio.

930 Interestingly, the performance of the models improves with the reduced fea-  
 931 ture set. K-Nearest Neighbors (KNN) achieves the highest performance in this

932 scenario, with an accuracy of 64.16%, precision of 64.97%, recall of 64.16%, and  
933 an F1-score of 63.75%. These results suggest that KNN benefits from using only  
934 the most significant features, showing a notable improvement over its performance  
935 when all 13 features are used.

936 **Chapter 5**

937 **Conclusion and**  
938 **Recommendations**

939 **5.1 Conclusion**

940 **5.2 Recommendations**

941 This special problem entitled Morphometric-Based Non-invasive Sex Identification  
942 of *T. granosa* focuses on creating a baseline study that will serve as a foundation  
943 for further studies involving *Tegillarca granosa*, blood cockles using machine learn-  
944 ing, deep learning, and computer vision technologies in determining the sex of the  
945 samples is a salient need in aquaculture practices. Thus, the proceeding rec-  
946 ommendations are the future applications to improve and have detailed analysis  
947 such as focusing on shape analysis, exploring other state-of-the-art CNN such as  
948 ResNet, SqueezeNet, and InceptionNet, and comparing the analysis result. Fur-  
949 thermore, the main goal of conducting this is to have the ability to identify the  
950 sex of the samples by taking real-time angles by rotating from the dorsal, lateral,  
951 and ventral.

952 Future studies could also invest in a much sturdier and more controlled envi-  
953 ronment by using a green background and positioning a webcam at a fixed angle.  
954 In addition, experiment with other image processing techniques such as scaling,  
955 rotating, and augmentation. The dataset can be utilized for further analysis us-  
956 ing deep learning and computer vision to make sense of the images gathered and  
957 discern sexual dimorphism for *T.granosa* or will serve as the basis for conducting  
958 similar studies to other bivalve species.
